ABSTRACT

Objectives: To characterize the main identified mutations on cystic fibrosis transmembrane conductance regulator (CFTR) in a group of children and adolescents at a cystic fibrosis center and its association with the clinical and laboratory characteristics.

Method: Descriptive cross-sectional study including patients with cystic fibrosis who had two alleles identified with CFTR mutation. Clinical, anthropometrical, laboratory and pulmonary function (spirometry) data were collected from patients’ records in charts and described with the results of the sample genotyping.

Results: 42 patients with cystic fibrosis were included in the study. The most frequent mutation was F508del, covering 60 alleles (71.4%). The second most common mutation was G542X (six alleles, 7.1%), followed by N1303K and R1162X mutations (both with four alleles each). Three patients (7.14%) presented type III and IV mutations, and 22 patients (52.38%) presented homozygous mutation for F508del. Thirty three patients (78.6%) suffered of pancreatic insufficiency, 26.2% presented meconium ileus, and 16.7%, nutritional deficit. Of the patients in the study, 59.52% would be potential candidates for the use of CFTR-modulating drugs.

Conclusions: The mutations of CFTR identified more frequently were F508del and G542X. These are type II and I mutations, respectively. Along with type III, they present a more severe cystic fibrosis phenotype. More than half of the sample (52.38%) presented homozgyous mutation for F508del, that is, patients who could be treated with Lumacaftor/Ivacaftor. Approximately 7% of the patients (7.14%) presented type III and IV mutations, therefore becoming candidates for the treatment with Ivacaftor.

Keywords: Cystic fibrosis; Mutations; Genetics; Phenotype; Child.

INTRODUCTION

Cystic fibrosis (CF) is a genetic autosomal recessive disorder, more common in Euro-descendant populations, caused by variations in the gene sequence which codifies the cystic fibrosis transmembrane conductance regulator (CFTR) protein.¹ This gene is located in the long arm of chromosome 7 (locus 7q31), and is divided in 27 exons, generating a protein composed of 1,480 amino acids.

The estimated prevalence in several countries is of 1 for every 2,800-3,500 live births.² In Brazil, about 1 out of 10 thousand live births presents with the disorder.³ Mutations in CFTR establish a multisystemic aspect for the disease, characterized by pulmonary, gastrointestinal and sweat gland disorders.³

Life expectancy in patients with CF has been improving, and, nowadays, more than half of them have reached adulthood.² Such an improvement, among other factors, is owed to the increment in innovative treatments and the advancement of interdisciplinary care addressed to the patient with CF.² Recently, specific therapies addressed to the CFTR channel, which are able to correct the basic flow, have been developed and approved for use in several countries. These targeted drugs aim at...
transferring CF therapy, making the prescription of

drugs more accurate.(6)

Some protocols include genetic evaluation to
complement neonatal screening and clinical diagnosis
of CF, allowing the identification of patients who
are eligible to mutation-specific therapies.(7) The
variants identified in CFTR are divided in six classes
of mutations, based on their functional effects.(1)
The relationship between genotype and the clinical
consequences of all variants, however, requires further
understanding.

This study aimed at reporting the main CFTR
mutations identified in a group of children and
adolescents followed-up at a multidisciplinary
center for CF treatment in the South of Brazil, and
at associating such mutations to specific clinical and
laboratory characteristics.

**METHOD**

This is a cross-sectional, descriptive study. Patients
who were followed-up at a reference center in the
South of Brazil were included. The subjects with
suggestive clinical history who were included had
their diagnosis confirmed by laboratory examinations
(sweat electrolyte test), and had the identification
of two mutations in the CFTR. Figure 1 presents the
flow chart of the inclusion of individuals in the study.

The reference center has multidisciplinary staff
composed of physicians, nutritionists, physical
therapists and psychologists, who regularly follow-up
more than 100 patients (children and adults). The
patients are periodically followed-up with clinical
examinations (assessment of nutritional status and
body mass index – BMI), laboratory examinations
(albumin, glucose, liver function and stool elastase,
according to indication) and spirometry (forced
expiratory volume in 1 second – FEV1). Besides, the
analysis of sputum culture or oropharyngeal swab
is routine, in order to identify the colonization by
*Pseudomonas aeruginosa* (PA). The molecular analysis
of CFTR is carried out for all patients with clinical
diagnosis (based on the symptoms and chloride in the
sweat > 60), but without a definitive genetic diagnosis,
in the following order: F508del genotype, kits for the
study of mutations and sequencing; the investigation
is interrupted when two alleles are identified.

The genotyping of the F508del mutation is the
most frequent one in the population with CF, so it
was presented in patients with clinical diagnosis.
Heterozygotic individuals, or the ones who did not
present with this mutation, carried out a panel of
mutations with commercial kits of 32 to 97 mutations.
In cases in which the genetic change had not been
identified in both alleles, the complete sequencing of

![Flowchart of the inclusion of patients in the study.](image-url)
the CFTR was performed. The analyses were conducted by different laboratories, according to the availability of the health system or private health insurance plan. All of the collected data (age, immunoreactive trypsin dosage – IRT, chloride in the sweat, genotype, colonization, spirometry and clinical aspects) were obtained based on the information from the patients’ charts. Simultaneously, a literature review was carried out regarding the phenotype described for the most frequent mutations found in our sample.

This study was approved by the Research Ethics Committee of Pontifícia Universidade Católica do Rio Grande do Sul (PUC-RS) and is registered by n. 49692115.7.0000.5336.

RESULTS

Of the 103 patients with CF followed-up at the multidisciplinary center, 58 (56.3%) have been genotyped. Of these, 42 (72.4%) were included in the study for presenting both known alleles of CFTR. Table 1 contains data referring to the sweat test and age of the patients, and Table 2 shows the clinical, nutritional, and pulmonary function characteristics according to the identification of the mutations in each one of the alleles. The most frequent mutation was class II, represented by F508del (p.Phe508del), present in 38 patients (90.48%), and comprehending 71.43% (60 alleles) of the total identified alleles. Among the patients who presented with alterations for p.Phe.508del, 57.89% were homozygous for the mutation. The second most common mutation was class I, with mutation G542X (p.Gly542X), present in six alleles (7.14%), followed by the mutations N1303K (p.Asn1303Lys) and R1162X (p.Arg1162X), also class I, in four alleles (4.76%) each.

Of the 42 patients analyzed, 11 (26.2%) had meconium ileus, in which the following mutations were identified: F508del, G542X and R1162X. All of these represented mutation F508del, and seven patients (63.6%) were homozygous for this mutation. Three patients (27.3%) pointed mutation G542X as the second allele, and one patient showed mutation R1162X.

Regarding nutritional status, seven patients (16.7%) had deficit, characterized by BMI being below the lower limit of normal before or after the condition was diagnosed, and in these cases the following mutations were identified: F508del, R1162X e R347X; all of them contained mutation F508del. Of these, four were homozygous for F508del, two presented R1162X, and one, mutation R347X.

The patients were colonized by different types of bacteria: Staphylococcus aureus (SA), Pseudomonas aeruginosa (PA), Burkholderia cepacia (BC), Haemophilus influenzae and Methicillin-resistant Staphylococcus aureus (MRSA). The most common bacteria was SA, present in 28 of the 42 analyzed patients. PA was observed in 14 patients, all of whom presented the allele F508del; nine (64.3%) were homozygous for this mutation. BC was present in four patients, who had mutations F508del (3/8 alleles), R1162X (2/8 alleles) and N1303K, 711+5G>A, 1078delT.

Data presented in mean and standard deviation; *only 1/3 of the patients had these data collected.
Regarding pulmonary function, of the 22 patients who were homozygous for the change in class II p.Phe508del, 12 underwent spirometry, with FEV1 values ranging from 24 to 100% of the predicted value. The lowest values were observed in patients aged more than 18 years, showing reduction in pulmonary function with age. Of the three heterozygous patients for both mutations F508del/N1303K, one of them underwent spirometry with FEV1 value being 77%, and this patient was also colonized by SA. Of the five patients who were heterozygous for both mutations, three presented FEV1 ranging from 72 and 100%; they were all aged more than 15 years, one colonized by PA, and the other two, by SA. Of the two patients who were heterozygous for both mutations F508del/R1162X, FEV1 corresponded to 46 to 54%, in percentile, and these patients were aged between 5 and 10 years. In cases in which mutations only appeared once (F508del/3272-26A>G, F508del/G85E, F508del/R1066C, F508del/G551D, P205S/3132delTG, N1303K/1078delT, 711+5G>A/R1162X), FEV1 ranged from 43 to 104% of the predicted value.

DISCUSSION

Genotype-phenotype associations in CF, modifier genes, epigenetic factors, and environmental influence help to understand the broad spectrum of disease manifestations, which can range between single to multisystemic involvement, and between mild to severe disease. (8)

In this sample of patients with CF, F508del was the most common mutation, affecting more than 50% of the homozygous individuals. This class II mutation, responsible for the incorrect processing of the CFTR protein, present in approximately 70% of the Caucasian population with CF (9), is considered as a severe mutation, showing the classic phenotype of the disease. Individuals who are homozygous for this mutation usually present with high sweat chloride test results (mean of 98 mEq/L), early signs of respiratory symptoms, reduced pulmonary function, pancreatic insufficiency and delayed growth (10). It is the most known and studied mutation that causes CF.

Three other mutations were observed often in our sample: G542X, R1162X and N1303K. Mutation G542X (class I), characterized by a change that results in the absence of the CFTR protein, was the second most prevalent in this sample of patients (six alleles, 7.14%), and its frequency is estimated between 2.7 and 8.5% in Brazil (11,12). This mutation is responsible for the high incidence of meconium ileus (13). In our sample, most patients who presented with one allele of the mutation G542X also had pancreatic insufficiency (66.7%). A study that assessed clinical variables in 148 patients with this mutation verified that all of them had pancreatic insufficiency, which shows its severity (14). Patients with mutation R1162X (class I) presented high sweat chloride test results (mean of 103 mEq/L), mild to moderate pulmonary disease and pancreatic insufficiency. Class II mutation N1303K is

MI: meconium ileus; PI: pancreatic insufficiency with laboratory confirmation; BMI: body mass index; PA: colonization by *Pseudomonas aeruginosa*; FEV1: Forced expiratory volume in 1 second; *only 1/3 of the patients had this data collected 1/3.

Data presented in mean and standard deviation or percentage and absolute number.

among the most common ones\textsuperscript{(10)} for patients with CF, whose frequency is higher than 1%, and shows great variation between countries and ethnicities.\textsuperscript{(15-17)} Considered as a severe mutation, its phenotype is related to severe pancreatic consequences, and may lead to pancreatic insufficiency and diabetes mellitus.\textsuperscript{(15,16,18)} Regarding pulmonary phenotype, the severity of the disease indicates great variability between the different mutations.\textsuperscript{(15,18)} In this sample, patients identified with mutation N1303K in one of the alleles had pancreatic insufficiency.

The other mutations that were found, being each of them presented in one patient, were revised next. Mutation 3132del TG (class I) is rare, and ongoing population studies\textsuperscript{(10)} will help to determine its disease phenotype. Mutation 711+5G>A (class I) is more common among Hispanic Americans and in Northeast Italy. A study that included two patients with this mutation associated with F508del showed that these patients had chronic colonization by PA and SA, liver disease and pancreatitis more often.\textsuperscript{(19)}

The class III G551D mutation, which is related to the obstruction of the chloride passage through the CFTR protein channel, is associated with pulmonary disease, pancreatic insufficiency, infection by PA and sweat test with increased values. Of the 2,915 patients analyzed, with mean age of 20 years, with this mutation and another mutation for CF, pulmonary function, expressed by spirometry predicted values (FEV1%), in children aged less than 10 years, ranged from 95 to 139%; among individuals aged from 10 to 20 years, from 78 to 131%, and for those aged more than 20 years, from 34 to 107%.\textsuperscript{(10)}

Mutation 3132del TG, when it comes to mean chloride values in the sweat test is 45 mEq/L, and most patients have sufficient pancreas. Mean age at the time of diagnosis is 33 years. According to clinical studies, when it is concomitant to other mutations, D1152H usually causes pulmonary symptoms; however, these are not severe and associated with prolonged survival rates.\textsuperscript{(27)} Mutation 1078delT (class I) can be phenotypically manifested by pancreatic insufficiency,\textsuperscript{(10)} and individuals who have it may present with cirrhosis and mild pulmonary disease.\textsuperscript{(10,29)}

Mutation R347H (class IV) is related with pancreatic insufficiency and infection by PA. Of the 161 patients analyzed, with mean age of 23 years who have this mutation and another one for CF, pulmonary function, expressed by the spirometry predictive value (FEV1%), in children aged less than 10 years ranged from 95 to 139%; among individuals aged from 10 to 20 years, from 78 to 131%, and for those aged more than 20 years, from 34 to 107%.\textsuperscript{(10)}

The presence of mutation D1152H (class IV), combined with another mutation that causes CF, does not manifest the disease in all patients. Individuals who have this mutation associated with another one, which is known to cause CF, must undergo frequent check-up sessions, even if asymptomatic.\textsuperscript{(10)} Most chloride values in the sweat test is 45 mEq/L, and most patients have sufficient pancreas. Mean age at the time of diagnosis is 33 years. According to clinical studies, when it is concomitant to other mutations, D1152H usually causes pulmonary symptoms; however, these are not severe and associated with prolonged survival rates.\textsuperscript{(27)} Mutation 1078delT (class I) can be phenotypically manifested by pancreatic insufficiency,\textsuperscript{(10)} and individuals who have it may present with cirrhosis and mild pulmonary disease.\textsuperscript{(10,29)}

Currently, the development of drugs which improve CFTR function have shown promising results in the course of the disease, and may be able to contribute with the increasing life expectancy in patients with CF. Two systemic modulators of CFTR were assessed in clinical trials involving patients with CF, and approved by the American agency Food and Drug Administration (FDA).

Ivacaftor (VX-770) is a drug that potencializes the CFTR regulator, increasing the ionic function in the cellular surface, improving the obstruction of airways due to the retention of water and increasing mucus purification. This drug can be used for patients who have one of the 33 mutations of classes III and IV — among them, mutations G551D, R347H and 1152H, present in three patients (7.14%) of this study.\textsuperscript{(30-33)}
Lumacaftor (VX-809) is a CFTR corrector, which increases the amount of protein located in the surface of the cell; its effect is added to Ivacaftor, whose effect potentializes the chloride channels.\(^{(33)}\) A study published in 2014, which included patients of 24 centers of cystic fibrosis in Australia, Belgium, Germany, New Zealand and the United States, showed that the association of Ivacaftor/Lumacaftor does not have significant effects for patients heterozygous for the class II mutation (p.Phe508del); however, patients who are homozygous for the mutation presented a reduction in the frequency of exacerbations and improvement of FEV1.\(^{(34)}\)

Recently, the FDA has approved the drug that combines Tezacaftor (VX-661) and Ivacaftor as therapy for patients with CF aged 12 years or more, who carry two copies of the F508del mutation, or for patients who are heterozygous for this mutation associated with a second mutation, which results in the residual function of CFTR. Tezacaftor helps the CFTR protein to dislocate to the cellular surface, and then Ivacaftor helps the ionic CFTR channel to stay open for longer periods of time. Results of two phase 3 studies showed that the treatment with this medication has significantly improved pulmonary function and other health measures in comparison to placebo, showing a favorable safety profile. In our sample of patients, 27 (64.2%) of them would potentially benefit from this drug.

In conclusion, the mutations more often identified were F508del and G542X, which have higher severity profiles. In our sample, 22 patients (52.38%) would be potential candidates for the use of the compound Lumacaftor-Ivacaftor, which has proven to be effective in subjects aged more than 6 years homozygous for the F508del mutation. Besides, three patients (7.14%) would be candidates for the use of Ivacaftor, drug that can be used in individuals who present with 33 class III or IV mutations, such as G551D, R347H and 1152H, which were present in these patients.
